Problem 1

How does the web server (e.g., eBay) identify users when you do the Internet shopping? Briefly explain how it works.

Write your solution to Problem 1 in this box

Problem 2

Suppose within your Web browser you click on a link to obtain a Web page. The IP address for the associated URL is not cached in your local host, so a DNS lookup is necessary to obtain the IP address. Suppose that n DNS servers are visited before your host receives the IP address from DNS; the successive visits incur an RTT (round-trip time) of RTT_1, RTT_2, ..., RTT_n. Further, suppose that the Web page associated with the link has a small amount of HTML text. Let RTT_0 denote the RTT between the local host and the server containing the HTML file. Assume zero transmission time. Suppose the HTML file references ten very small objects on the same server. How much time elapses from when the client clicks on the link until the client receives all objects with:

(a) Non-persistent HTTP with no parallel TCP connections?

(b) Non-persistent HTTP with the browser configured for 5 parallel connections?

(c) Persistent HTTP with no parallel TCP connections?

(d) Persistent HTTP with the browser configured for arbitrarily many parallel connections?

Write your solution to Problem 2 in this box

Problem 3

Suppose Bob joins a BitTorrent torrent, but he does not want to upload any data to any other peers (so called free-riding).

(a) Bob claims that he can receive a complete copy of the file that is shared by the swarm. Is Bob's claim possible? Why or why not?

(b) Bob further claims that he can further make his "free-riding" more efficient by using a collection of multiple computers (with distinct IP addresses) in the computer lab in his department. How can he do that?

Write your solution to Problem 3 in this box

Problem 4

How does SMTP marks the end of a message body? How about HTTP? Can HTTP use the same method as SMTP to mark the end of the message body?

Write your solution to Problem 4 in this box

Problem 5

Suppose your department has a local DNS server for all computers in the department.

(a) Suppose you are an ordinary user (i.e., not a network/system administrator). Can you determine if an external Web site was likely accessed from a computer in your department a couple of seconds ago? Explain.

(b) Now suppose you are a system administrator and can access the caches in the local DNS servers of your department. Can you propose a way to roughly determine the Web servers (outside your department) that are most popular among the users in your department? Explain.

Write your solution to Problem 5 in this box
